Introduction

- Fecal based sampling techniques do not capture the taxonomic and functional complexity of the entire GI tract
- A more nuanced understanding of the GI microbiota is required to understand its ecology and niche specificity
- Little is know about the connection between biogeography and aging

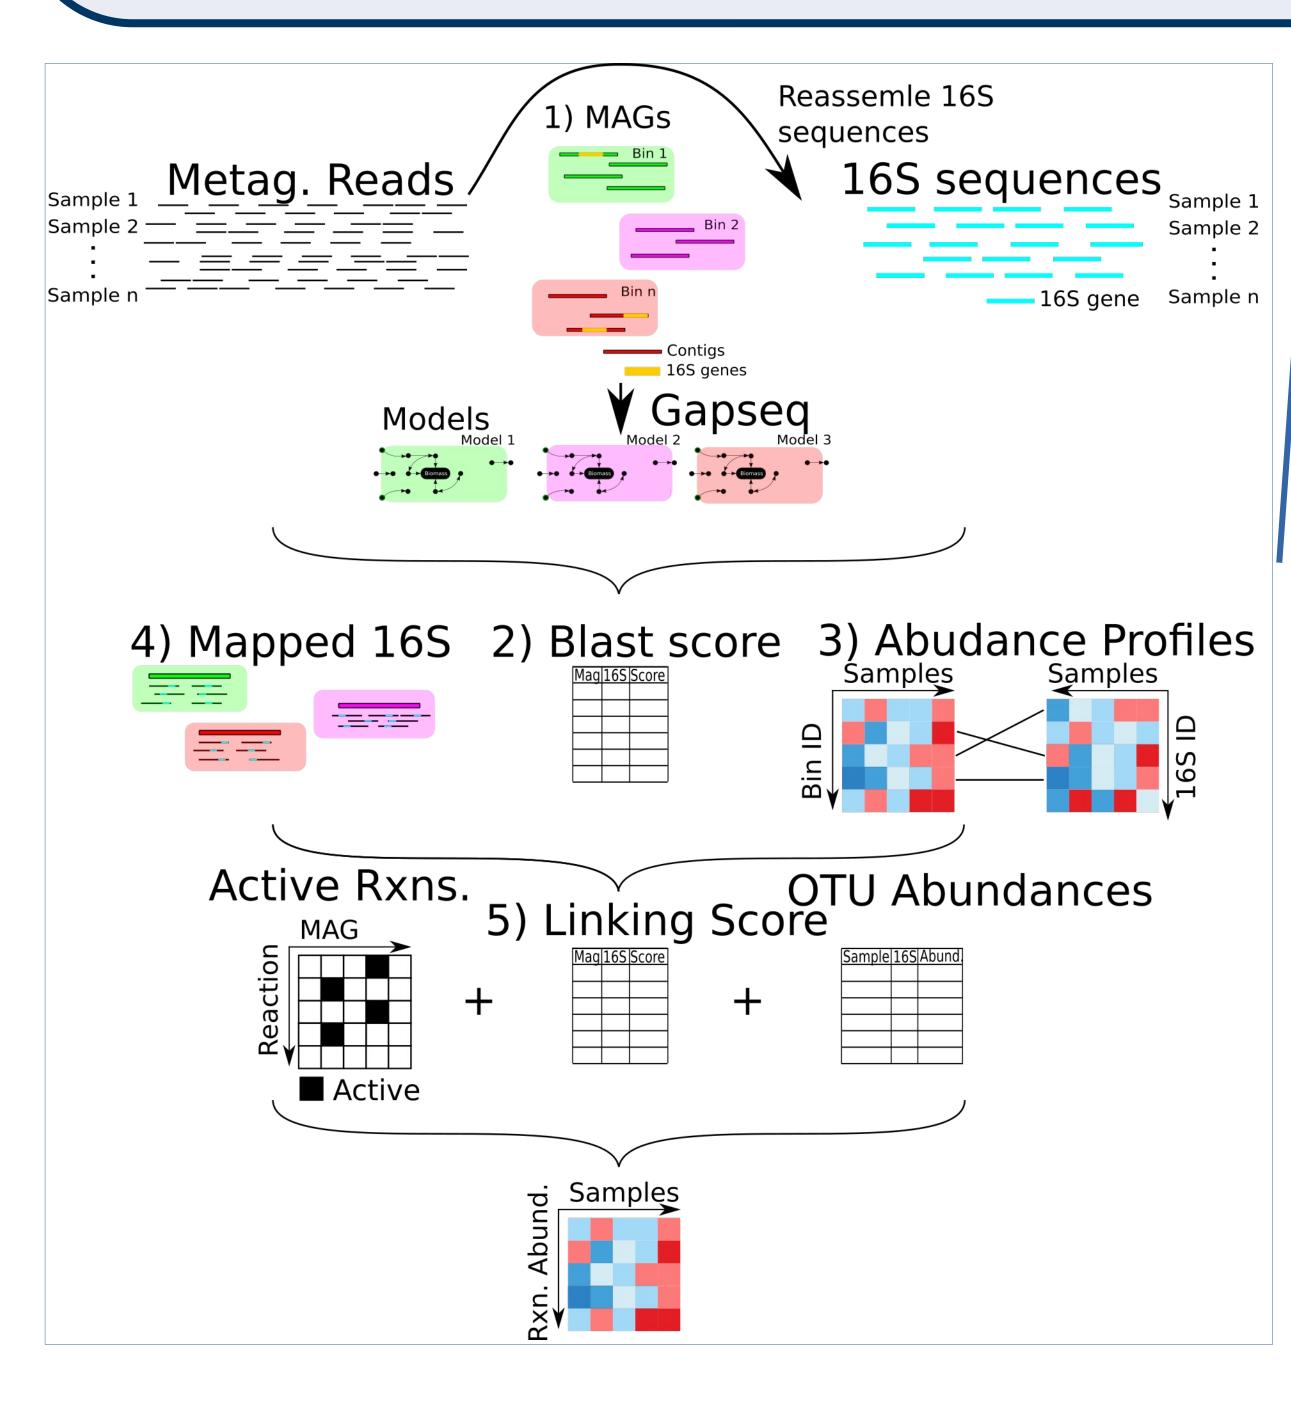

Goals

- Establish a pipeline to connect 16S information to metabolic models
- Investigate taxonomic and functional differences between the gastrointestinal sites through different age groups

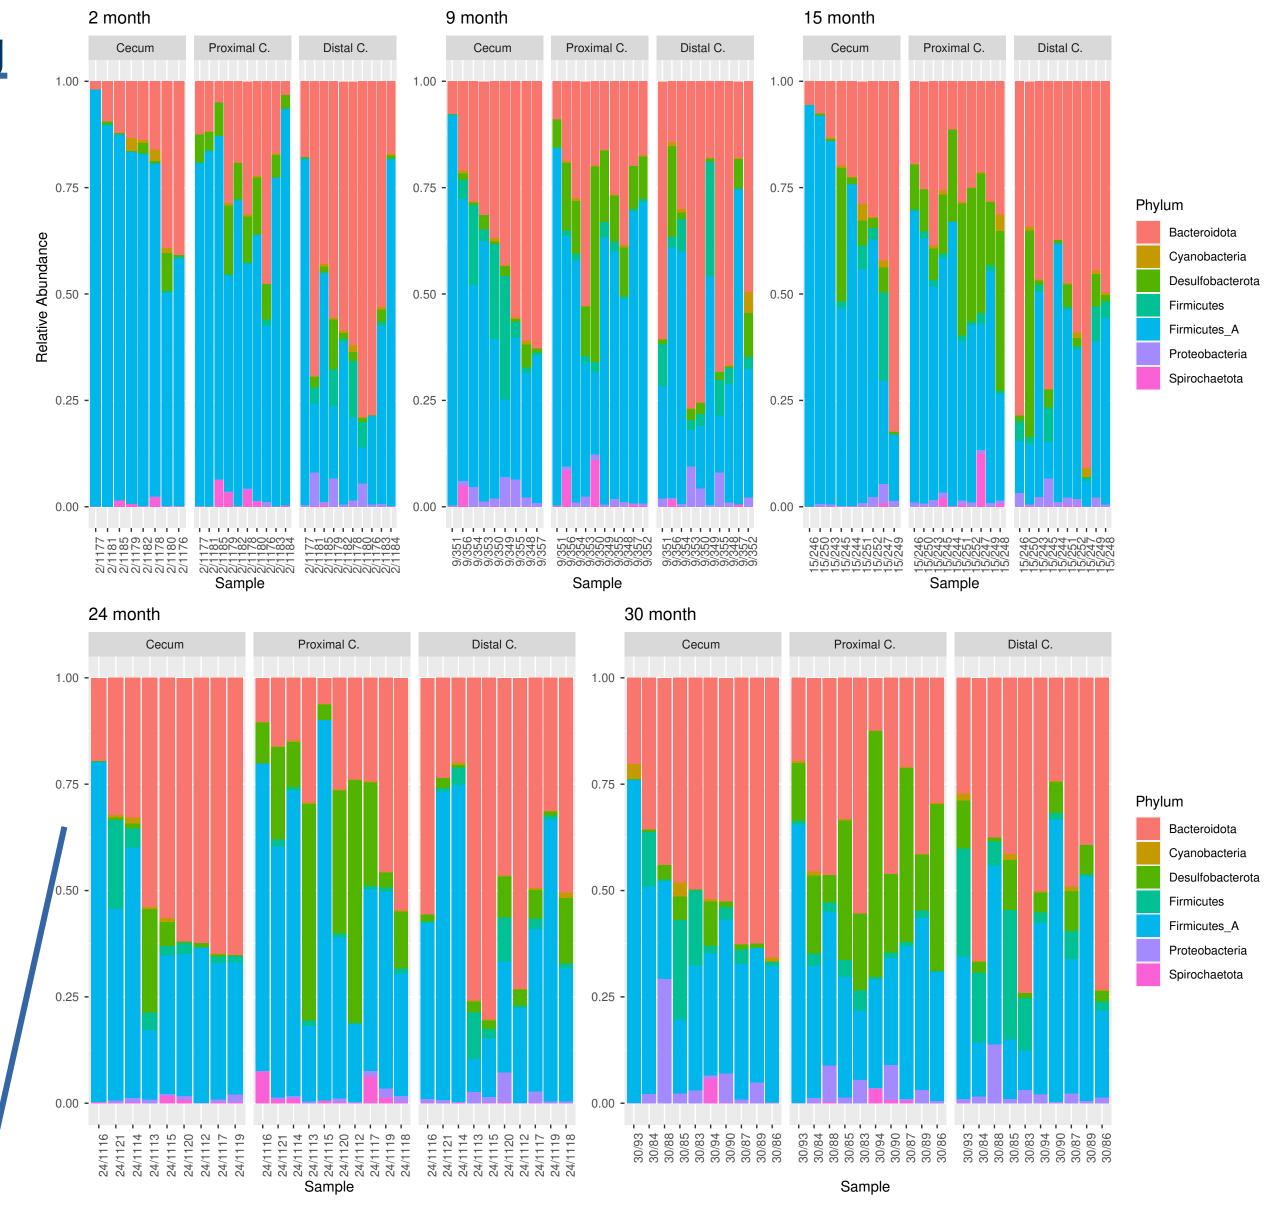

Future work

- Expand Taxonomic Diversity: Increase the taxonomic diversity within our simulation to better represent microbial diversity.
- Improve Realism and Effectiveness: Enhance the realism and effectiveness of the simulation by adopting community-driven modeling approaches. For example, consider using secreted metabolites from the cecum as a dietary component for the microbiota in the proximal colon.
- Incorporate Host-Related Factors: Include host transcriptomic data to account for the hostmicrobiome relationship.
- Verification: Employ spacial metabolomics to verify predictions

1. 16S-Model linking

- Enables the linking of taxonomic information (16S) to functional information (metabolic models)
- Based on an approach from Lesker et al, 2020 that links 16S to MAGs
- 1) Dedicated assembly of 16S genes
- 2) Identifying 16S genes in MAGs (Blast)
- 3) Correlating 16S and MAG abundances across samples
- 4) Map 16S to MAGs
- 5) Link all this information into a MAG-16S linking score. Ultimately use this to link 16S to metabolic models created from the MAGs

2. GI Taxonomy

- Increasing rel. abundance of *Bacteroidota* from the cecum to the distal c. in young and adult mice
- Increased rel. abundance of *Desulfobacterota* in the proximal C. across all age groups compared to the other sites
- Aged mice show less drastic differences in rel. *Bacteroidota* abundance 15M

TCA cycle

L–glutamine synth.

partial TCA cycle

glyoxylate cycle

reductive TCA cycle

L-tryptophan degr.

L-tyrosine degr.

L-glutamate degr.

laurate synth.

gondoate synth.

mycolate synth.

streptorubin B synth.

cis-vaccenate synth.

stearate synth.

palmitate synth.

fatty acid synth.

lipid synth.

lipid A synth.

petroselinate synth.

fatty acid synth. init.

fatty acid elongation -- saturated

5-aminoimidazole ribonucl. synth

ADP-L-glycero-..-D-manno-heptose synth.

pyridoxal 5'-phosphate synth.

oleate synth.

L-phenylalanine degr.

poly wall teichoic acid synth.

8-amino-7-oxononanoate synth.

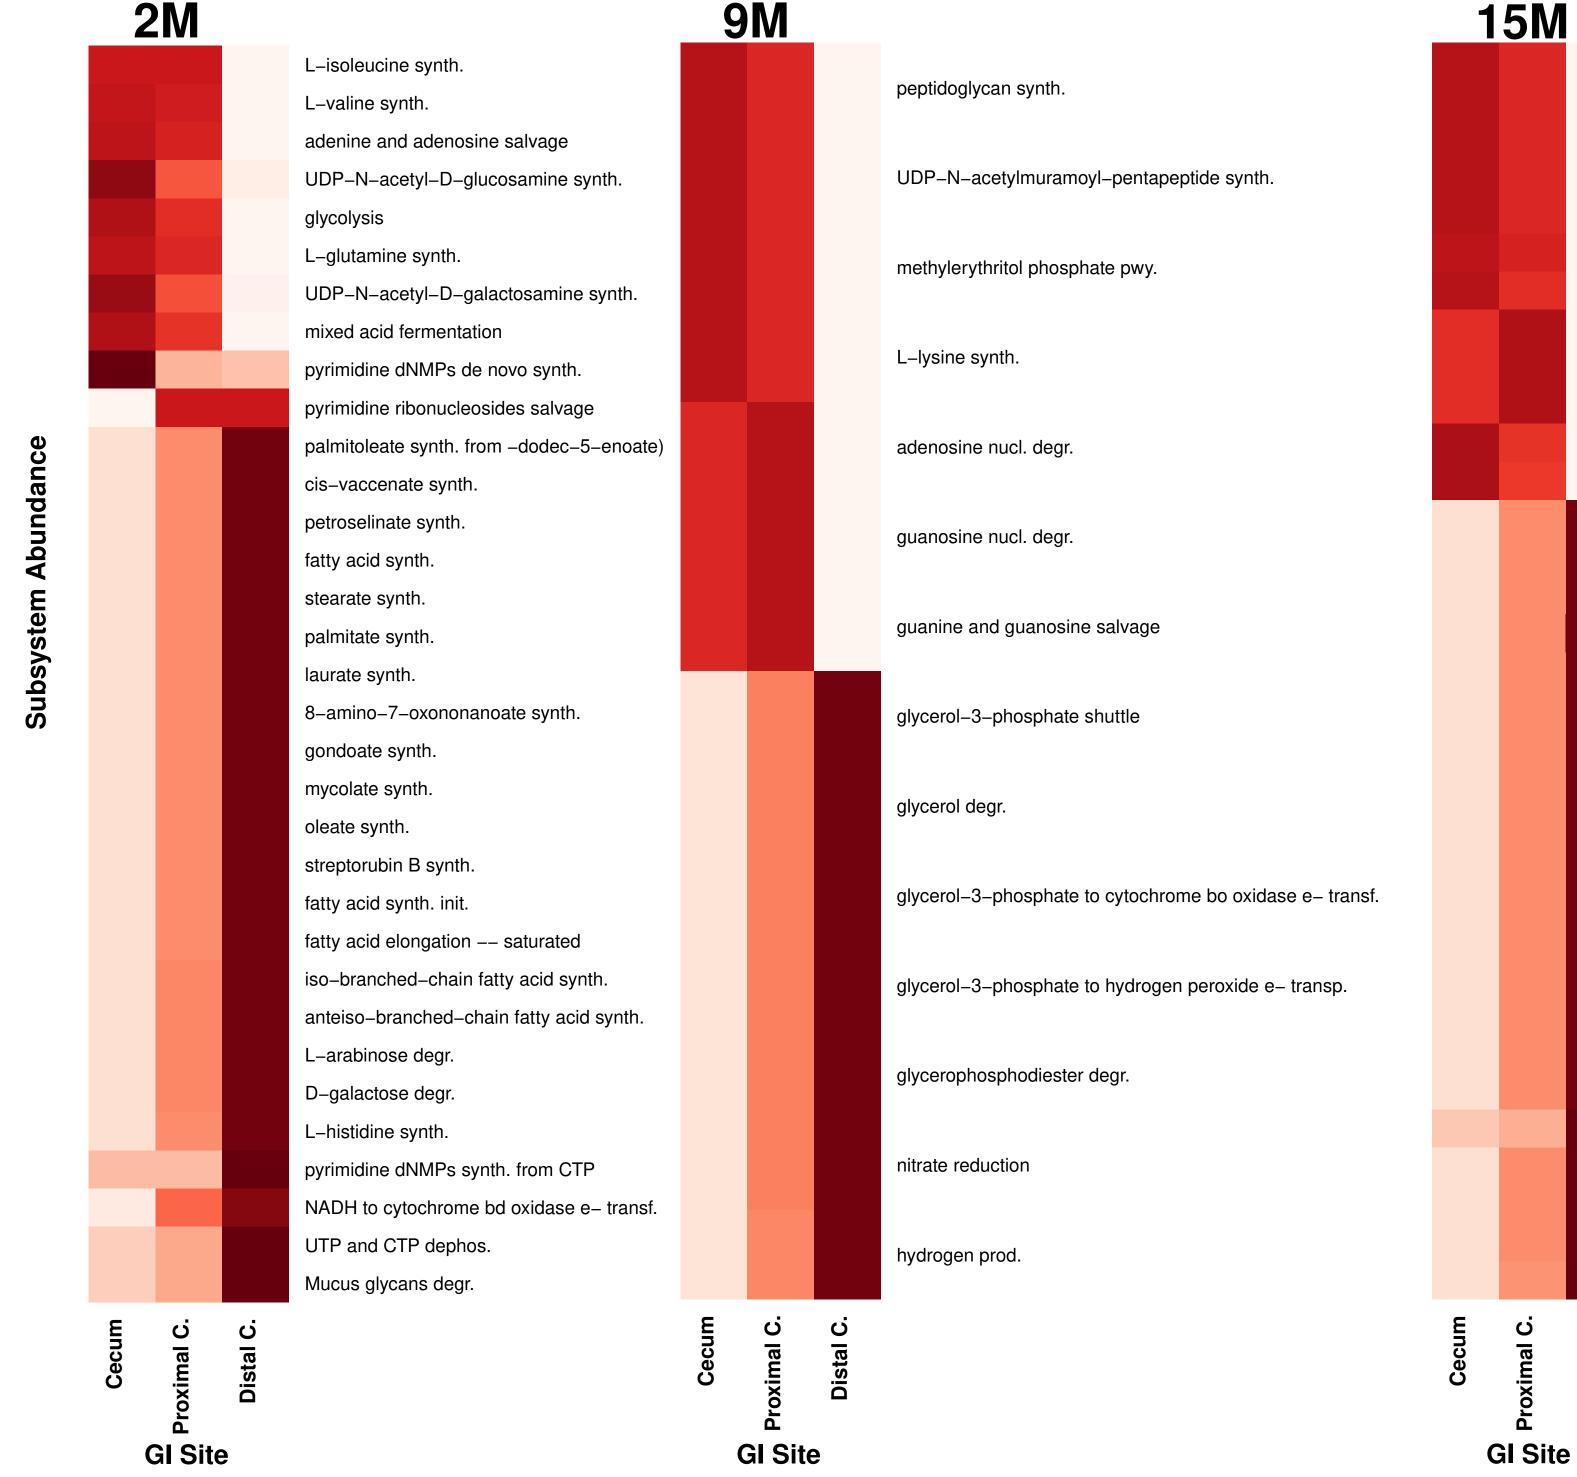

iso-branched-chain fatty acid synth.

anteiso-branched-chain fatty acid synth.

palmitoleate synth. -dodec-5-enoate)

mixed acid fermentation

methylaspartate cycle

3. Functional enrichment

- First three age groups show different region-specific functions
- No functional differences along the GI tract could be detected in 24 and 30 months old
- 2 month old mice show increased mucin glycan degradation in the distal colon
- Amino acid synthesis more active in the cecum and proximal c. of young mice Amino acid degradation more active in the cecum and
- proximal c. of the GI tract in 15 month old Increased (long) fatty acid synthesis along the GI tract in
- 2 and 15 months old
- Mixed acid fermentation (SCFA production) most active in the beginning of the GI tract in 2 and 15 months old

4. Results

- Established and verified a Snakemake based pipeline to connect metabolic models and 16S information
- The three GI sites show clear functional and taxonomic differences in young and adolescent mice
- No functional differences detectable in 24 and 30 month old mice
- Mixed acid fermentation (SCFA production) most active in the beginning of the GI tract in 2 and 15 months
